data with parity across three or more disks.
Server storage can take various forms, including:
Hard Disk Drives (HDDs): Traditional mechanical hard drives that use rotating disks to store data. HDDs are commonly used for cost-effective storage solutions, but they may be slower compared to newer storage technologies.
Solid-State Drives (SSDs): SSDs use flash memory to store data, offering significantly faster read and write speeds compared to HDDs. They are ideal for applications and workloads that require high performance and low latency.

Virtual disks

The New Virtual Disk wizard asks you to assign the following:

- A level of data protection
- A level of storage provisioning

Data protection

Use one of the resiliency types below:

- **Mirror (recommended)**–One or two extra copies of each file are written across a stripe that includes two or more hard drives. Mirroring hard drives reduces capacity by as much as 50% but it also offers enhanced performance when compared to parity.
- **Parity**–Parity information is written alongside data across a stripe that includes three or more hard drives. Parity offers greater capacity than mirroring but performance is reduced. Parity is a very good option for archival environments.
- **Simple (No data protection)**–Though it provides the best performance, **choosing Simple can lead to data**
